

Flex Shrink in CSS

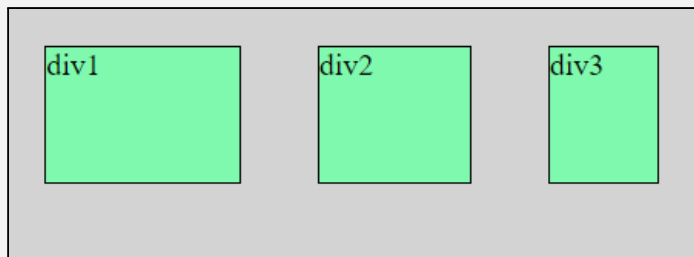

Overview

The flex-shrink property specifies the ratio with which a **flex item shrinks relative to the other flex items** when there is some extra space available. This is just the opposite of flex-grow.

Here, also the range of value is from **0(zero) to any positive number**. Zero means width would not change.

Example :

```
<div class="flex-container">
  <div style="flex-shrink: 0;">div1 </div>
  <div style="flex-shrink: 2;">div2 </div>
  <div style="flex-shrink: 4;">div3 </div>
</div>
```

Browser :

- ❖ Here, only the div2 and div3 shrink, when the width of the container is decreased. Also, div3 decreases twice as much as div2. Now, width of div1 is 100px, div2 is 70px and div3 is 40px.
